0.1 Recursion

0.1.1 Teacher's guide

Emne Rekursion

Sværhedsgrad Middel

0.1.2 Introduction

Recursion is a central concept in functional programming, and is usually used instead of for and while loops. The following exercise thus train the use of recursion.

0.1.3 Exercise(s)

- **0.1.3.1:** Use List.fold and List.foldback and your own implementations from Assignment 5 to calculate the sum of the elements in [0 . . n], where n is a large number.
- **0.1.3.2:** The Collatz conjecture is a famous unsolved problems in mathematics¹. The conjecture states that for any integer larger than 0, recursively applying,

$$f(n) = \begin{cases} \frac{n}{2} & \text{if } n\%2 = 0\\ 3n + 1 & \text{if } n\%2 = 1 \end{cases}$$

will always lead the value 1.

(a) Implement a non-recursive function collatzStep : n:int -> int that gives the next number in the collatz sequence. Examples:

```
collatzStep 1 = 1
collatzStep 2 = 1
collatzStep 3 = 10
collatzStep 9 = 28
```

The function should use pattern matching.

(b) Implement a recursive function that counts the number of steps in the collatz sequence starting at n:

```
collatzStepsHelper : count:int -> n:int -> int:
```

The function should use pattern matching, recursion and the previous function collatzStep to compute each intermediate step of a sequence.

(c) Implement a non-recursive function collatzSteps : n:int -> int that simply calls collatzStepsHelper with an initial count of 0.

https://en.wikipedia.org/wiki/Collatz_conjecture

- **0.1.3.3:** Write a function, fac : n:int \rightarrow int, which calculates the faculty function $n! = \prod_{i=1}^{n} i$ using recursion.
- **0.1.3.4:** Consider the factorial-function,

$$n! = \prod_{i=1}^{n} i = 1 \cdot 2 \cdot \dots \cdot n \tag{1}$$

(a) Write a function

fac : n:int -> int

which uses recursion to calculate the factorial-function as (1).

- (b) Write a program, which asks the user to enter the number n using the keyboard, and which writes the result of fac n.
- (c) Make a new version,

fac64 : n:int64 -> int64

which uses int64 instead of int to calculate the factorial-function. What are the largest values n, for which fac and fac64 respectively can correctly calculate the factorial-function for?

- **0.1.3.5:** Make your own implementation of List.fold and List.foldback using recursion.
- **0.1.3.6:** The greatest common demoninator of 2 integers t and n is the greatest number c, which integer-divides both t and n with 0 remainder. Euclid's algorithm² finds this greatest common denominator via recursion:

$$\gcd(t,0) = t,\tag{2}$$

$$\gcd(t,n) = \gcd(n,t \% n),\tag{3}$$

where % is the remainder operator (as in F#).

(a) Implement Euclid's algorithm as the recursive function:

- (b) Test your implementation.
- (c) Make a tracing-by-hand on paper for gcd 8 2 and gcd 2 8.
- **0.1.3.7:** Write a function lastFloat: float list -> float that, using recursion, returns the last element of the argument list if the list is non-empty and returns the float value NaN if the argument list is empty.

For example, the call lastFloat [2.1;4.2] should return the float value 4.2 and the call lastFloat [] should return the value NaN.

- **0.1.3.8:** Write a function length: 'a list -> int that calculates the length of the argument list using recursion. The function should make use of pattern matching on lists.
- 0.1.3.9: Write a tail-recursive function lengthAcc: acc:int -> xs:'a list -> int that calculates the sum of acc plus the length of xs using tail-recursion. For instance, a call lengthAcc 0 xs should return the length of xs, and a call lengthAcc n [] should return the value n.

²https://en.wikipedia.org/wiki/Greatest_common_divisor

0.1.3.10: Write a function map: ('a -> 'b) -> 'a list -> 'b list that takes a function and a list as arguments and returns a new list of the same length as the argument list with elements obtained by applying the supplied function on each of the elements of the argument list. The function should make use of recursion and pattern matching on lists.

As an example, a call map $(fun x \rightarrow x+2)$ [2;3] should return the list [4;5].

- **0.1.3.11:** Write a function pow2: n:int \rightarrow int that calculates the value 2^n using recursion. The function should return the value 0 when n < 0.
- **0.1.3.12:** Using Steps 1, 3, 5, 7, and 8 from the 8-step guide
 - (a) write a recursive function which takes two integer arguments x and n and returns the value x^n .
 - (b) write another function wich takes one argument (x, n) and calls the former.

Document both functions using the <summary>, <param>, and <returns> XML tags. Consider what should happen, if n < 0, and whether there is any significant difference between the call of the two functions.

- **0.1.3.13:** Write a function, sum : n:int \rightarrow int, which calculates the sum $\sum_{i=1}^{n} i$ using recursion. Make an implementation using a while loop, compute a table for the values n = 1..10 and compare the results. Discuss the difference between the two methods.
- **0.1.3.14:** The following code calculates the sum $\sum_{i=0}^{n} i$ using recursion and 64-bit unsigned integeres.

```
let rec sum (n: uint64) : uint64 =
  match n with
    OUL -> OUL
    | _ -> n+sum (n-1UL)

let n = uint64 1e4
printfn "%A" (sum n)
```

Depending on the computer, this program runs out of memory for large values of n, e.g., not many computers can run this program when n = uint64 1e10. The problem is, that the algorithm is not using tail recursion.

- (a) Explain why this is not tail recursion.
- (b) Run the code on your computer and empirically find a small *n* for which the program runs out of memory on your computer.
- (c) Rewrite the algorithm to become tail recursive by including the accumulated sum as the argument:

```
sum (acc: uint64) -> (n: uint64) -> uint64
```

and check that this does not run out of memory for the above identified n. Try also bigger.

- (d) For which values of *n* would the tail recursive version break and why?
- **0.1.3.15:** Write a function sum: int list -> int that takes a list of integers and returns their sum. The function must traverse the list using recursion and pattern matching.

0.1.3.16: Consider the following sum of integers,

$$\sum_{i=1}^{n} i \tag{4}$$

This assignment has the following sub-assignments:

(a) Write a function

sum : n:int -> int

which uses pattern-matching and recursion to compute the sum $1+2+\cdots+n$ also written in (4). If the function is called with any value smaller than 1, then it is to return the value 0

(b) By induction one can show that

$$\sum_{i=1}^{n} i = \frac{n(n+1)}{2}, n \ge 0 \tag{5}$$

Make a function

simpleSum : n:int -> int

which uses (5) to calculate $1 + 2 + \cdots + n$ and which includes a comment explaining how the expression implemented is related to the mentioned sum.

- (c) Write a program, which asks the user for the number n, reads the number from the keyboard, and write the result of sum n and simpleSum n to the screen.
- (d) Make a program, which writes a table to the screen with 3 columns: n, sum n and simpleSum n. The table should have a row for each of n = 1, 2, 3, ..., 10, and each field must be 4 characters wide. Verify programmatically that the two functions calculate identical results.
- (e) What is the largest value *n* that the two sum-functions can correctly calculate the value of? Can the functions be modified, such that they can correctly calculate the sum for larger values of *n*?
